Abstract

Purpose – The purpose of this study is to evaluate food supply chain stakeholders' intention to use Industry 5.0 (I5.0) drones for cleaner production in food supply chains.

Design/methodology/approach – The authors used a quantitative research design and collected data using an online survey administered to a sample of 264 food supply chain stakeholders in Nigeria. The partial least square structural equation model was conducted to assess the research's hypothesised relationships.

Findings – The authors provide empirical evidence to support the contributions of 15.0 drones for cleaner production. The findings showed that food supply chain stakeholders are more concerned with the use of 15.0 drones in specific operations, such as reducing plant diseases, which invariably enhances cleaner production. However, there is less inclination to drone adoption if the aim was pollution reduction, predicting seasonal output and addressing workers' health and safety challenges. The findings outline the need for awareness to promote the use of drones for addressing workers' hazard challenges and knowledge transfer on the potentials of 15.0 in emerging economies.

Originality/value – To the best of the authors' knowledge, this study is the first to address 15.0 drones' adoption using a sustainability model. The authors contribute to existing literature by extending the sustainability model to identify the contributions of drone use in promoting cleaner production through addressing specific system operations. This study addresses the gap by augmenting a sustainability model, suggesting that technology adoption for sustainability is motivated by curbing challenges categorised as drivers and mediators.

Keywords Industry 5.0 drones, Food supply chains, Emerging economy, Sustainability, Cleaner production

Paper type Research paper

1. Introduction

The contributions of agriculture to economic growth in emerging economies are well-documented. For instance, a report by The World Bank (2022) showed that in 2018, agriculture's contribution to the gross domestic product (GDP) in emerging economies was over 25%. The notion is that the accurate development and dissemination of agricultural products would reduce poverty, raise incomes and facilitate

Supply Chain Management: An International Journal 29/3 (2024) 468–496 © Emerald Publishing Limited [ISSN 1359-8546] [DOI 10.1108/SCM-01-2023-0045] economic growth (Zeng *et al.*, 2015). However, the global population explosion, agriculture security and safety (Ge *et al.*, 2016; UN, 2022) and environmental concerns have threatened agriculture operations (Adams *et al.*, 2021). Moreover, the recent pandemic further highlighted the vulnerabilities of the agricultural sector, evident through disruptions in what are predominantly human-oriented production processes (Choudhury *et al.*, 2020). Also, transportation issues and labour shortages, which meant overreliance on inexperienced workers', often under informal or casual arrangements, have affected food production (Ahmed *et al.*, 2021).

Received 30 January 2023 Revised 21 May 2023 24 August 2023 Accepted 2 October 2023

Emerging digital technologies have transformed the way in which organisations operate and manage their supply chains (Frederico et al., 2019), thus it is unsurprising that research on technology use is considered pertinent within the agricultural domain (Liu et al., 2020). Hence, there are renewed calls for innovative solutions in tackling challenges faced in the agricultural sector, including the use of technology for cleaner production. It is particularly relevant since emerging technologies have the potential to respond to disasters and societal challenges effectively and efficiently (Dennehy et al., 2021). Industry 4.0 (I4.0) and more notably, the advent of Industry 5.0 (I5.0) applications, including smart farming, blockchain, cloud computing, drones, precision agriculture, connected applications and real-time virtualisation, have been suggested to increase production efficiencies by tackling food supply operation challenges (Saiz-Rubio and Rovira-Más, 2020; Panetto et al., 2020).

Despite the pivotal role the food sector plays on the global scale, and the apparent benefits I5.0 related techniques can have, the uptake has been predominantly slower across food supply chains when compared with other manufacturing industries (Duong *et al.*, 2020). To achieve this, focus must shift from the technology and process to people. Preuss and Fearne (2022) highlight the importance of studying supply chain stakeholders, given their role within supply chain in achieving sustainability goals. Hence, there is a need to understand human-related factors, which impede the uptake of such technologies within food supply chains.

While Michels et al. (2020) examined the adoption of drones by farmers, their study is based in Germany, which is a developed economy. Other studies have focused on understanding the adoption of technology in agricultural supply chains, such as their attitudes towards electronic identification (Lima et al., 2018), agricultural technology extension modes (Gao et al., 2020) and photovoltaic agriculture (Li et al., 2021). Yet, a criticism of I4.0 literature is that it has largely focused on technical perspectives, largely overlooked human factors (Grabowska et al., 2022), and focused more on profit-maximisation (Oláh et al., 2020), at the expense of sustainability. It can be argued that I5.0 is the ideal lens to explore the interplay between innovation, sustainability and food supply chains, as it shifts the focus solely on technology, as is the case for I4.0 (Erboz et al., 2022), towards a more encompassing approach, in which it attempts to consolidate resilience, sustainability and human-centricity with advanced technologies (Ivanov, 2023). Moreover, Maddikunta et al. (2022) highlight the potential of I5.0 in overcoming challenges posed by the pandemic, such as optimising supply chains. Thus, there is a need for more studies exploring the potential of I5.0, drones in food supply chains across emerging economies, such as Nigeria, given majority of the world's top ten countries that grow food are emerging economies (The World Bank, 2022).

For example, Rejeb *et al.* (2023) conclude that drones contribute significantly positively to the logistical issues by reducing delivery time and cost, as well as increasing flexibility and sustainability. The research also highlights a salient feature of the drone in resulting into a net-positive environment by reduced carbon emission, compared to the utilisation of fossilfuel machinery in agricultural activities, resulting in Supply Chain Management: An International Journal

Volume 29 · Number 3 · 2024 · 468–496

environmental sustainability. The investigation also suggests that looking through the lens of social sustainability, the adoption of drone technology has the potential to decrease the vulnerability and intricacy of various tasks. For instance, by using drones, critical safety issues tied to hazardous agricultural-field terrain inspections, such as steep-sloped and tall structure in vertical farming activity, and pesticide application, can be effectively mitigated. These views are shared by Damoah et al. (2021) who investigated the potential benefits of the use of AI-drones against the backdrop of healthcare supply chain (HSC), in Ghana. The investigation unveils that the AI-drones use impacted positively on the climate sustainability. This has been made possible through reduced carbon emission as the result of the deployment of carbon and noise-free drones in the delivery of emergency medical products to health-care centres. Further to that, the adoption of medical drones in the health-care system improves societal and economic conditions by lowering mortality rates contributed by timely delivery of supplies, better coordination of health-care supplies, and potentially leading to enhanced social and economic well-being for the population. Additionally, the implementation of medical drones contributes to the long-term corporate sustainability of the organisation involved in the initiative.

A host of studies carried out in the realm of health-care sustainability agree that the use of AI-drone in HSC or medical drone brought numerous social and environmental benefits, leading to sustainability. Regardless, its use in rural HSC is still at infancy, mainly due to lack of government regulations, which then leads to the lack of commitment in drone adoption (Koshta *et al.*, 2022). As such, the research suggests future work to understand and assess the challenges to drone technology adoption, particularly in the context where small artificial intelligence (AI) drones are used to perform tasks such as spraying, temperature sensing and transporting small deliveries.

In recent times, overcoming the adverse impact of excessive, unrestricted pesticide use has received growing attention, particularly within an emerging economy context (Owusu and Abdulai, 2019). Agritech companies are increasingly growing, creating reliable data-based systems that connect farmers across the country. However, more needs to be done because the minimal adoption of farming technology, ineffective agricultural-service delivery culture, and low incentives for start-ups derail progressive, competitive farming and agribusiness. Agriculture in emerging economies, such as Nigeria, is highly affected by low skills, and it is supported largely by humans rather than machinery. Agricultural processing is deprived of value-adding content, which leads to excessive post-harvest losses annually (Ekiyor et al., 2019). Other constraints include a poor infrastructural base, inadequate stakeholders' long-term financing structure and a poor market base (Adebiyi et al., 2020).

Focusing on emerging economies is important as there is a dearth of research and development in agriculture supply chains, especially across African nations (Swinnen and Kuijpers, 2019). Such emerging economies also face other challenges, such as lacking infrastructure; higher social inequalities and informality; as well as greater degree of corruption (Pereira *et al.*, 2021). Given these challenges, including that of poverty and food security faced by these

economies, it is pertinent to understand how technological infrastructure can facilitate the growth of agriculture in emerging economies (Fuglie *et al.*, 2020). Similarly, the literature examining the contributions of innovative solutions in enhancing food supply chains in emerging economies is evasive (Said Mohamed *et al.*, 2021), where existing studies have primarily focused on technological factors (Moshref-Javadi *et al.*, 2020).

This study engages in the debate for the potential of drones in agricultural supply chains, including its capacity for cleaner production (Mubarik et al., 2021; Mahroof et al., 2021). For instance, the use of drones has been suggested as a realistic solution to global food challenges and shortages (Spanaki et al., 2021). Similarly, Strandhagen et al. (2022) showed that I4.0 sustainability in supply chains through optimised automation, enhanced collaboration, efficient knowledge sharing and enhanced working conditions. Yet, more research is needed to understand the potential of I5.0 drones within agricultural supply chain contexts. In support of this, Panagou et al. (2023) outlines the need for more empirical research which places focus on human-centricity with I5.0 research. Accordingly, this research focuses on the following research questions:

- *RQ1.* What factors influence food supply chain stakeholders to adopt I5.0 drones for cleaner production?
- *RQ2.* Does the application of I5.0 drones solve food supply chain challenges?

We approached our research objective by adopting a parsimonious sustainability model developed by Mahroof *et al.* (2021), which measured specific activities in agricultural operations while incorporating sustainability. The model was considered appropriate as it captured precise aspects of agricultural production that could influence stakeholders' uptake of I5.0 drones, which have not been considered in other models (Featherman *et al.*, 2021). As such, we combined existing literature to measure a broad selection of variables including pesticide hazards, prediction accuracy, plant disease eradication, workers hazard and planting accuracy. Our research, therefore, aims to understand the determinants of drone use among stakeholders in a food supply chain from an emerging economy context.

This article is structured as follows. Following details relating to the context of this research, Section 2 presents a literature review, which expands on research and development in agriculture supply chains, followed by hypotheses development and the adopted conceptual model. Section 3 presents the methodology used, followed by the result and analysis in Section 4. The discussion of results and conclusion are presented in Sections 5 and 6, highlighting the research limitations and future research agenda.

1.1 Emerging economy context: Nigeria

Agricultural technologies can lead to financial freedom for emerging economies (Odularu, 2020), thus, raising awareness regarding technological advancements within food production is necessary for contexts such as Nigeria, where farmers are heavily reliant on traditional methods. Within such contexts, food production is contingent on seasonal rains, sparsely available irrigation systems and limited pest control *Volume* 29 · *Number* 3 · 2024 · 468–496

mechanisms (Muzari *et al.*, 2012). With it rising Nigerian populace, expected to reach 400 million by 2050 (FAO, 2021) and its aspiring export portfolio, it is pertinent to explore the benefits of enhanced technologies such as I5.0 to ensure its agricultural sector can remain both competitive and sustainable.

Thus, the Nigeria context for this research is relevant as it may signpost lessons to other emerging economy contexts. More importantly, the agriculture sector plays a highly significant role in Nigeria's economic development and progression, serving as the primary source of livelihood for up to 30% of 250 million Nigerians (FAO, 2022). It also accounts for 22.35% of its GDP (FAO, 2022). Notwithstanding the contribution of agriculture to Nigeria's economy, the sector is saddled with several challenges. These include climate change, low technology utilisation, harvest losses and poor market access, affecting farming operations and productivity (Ayittey, 2016).

Nigeria's agricultural practice is diversely represented through its multi-indigenous and multi-cultural setup. It functions with every clan having specific methods, which presents an exciting platform to explore (Avittey, 2016). Despite the enormous prospects that exceed farming to include animal husbandry and fishing, there is a struggle for the Nigerian Government to provide the required infrastructure. This is significant, as environmental factors, such as government policies and investment, are shown to play a key role in the adoption of technology (Ali et al., 2022). The sector suffers losses in earnings attributed mainly to ineffective leadership resulting in poor technological adoption (Agbachom et al., 2019; Osabohien et al., 2019). Meaning the diffusion of technology in farming is at its lowest (Baiyegunhi et al., 2019). The proposed research will offer further insights into factors which impede and support adoption of technology within Nigeria's supply chain stakeholders.

2. Literature review: research and development in agriculture supply chain

2.1 Technology adoption in agriculture supply chain

There remains limited research exploring agricultural stakeholders' intentions towards adopting I5.0 drones, particularly from an emerging context. Extant literature suggests institutional, economic and technological factors (Takahashi et al., 2020). However, technological adoption within agricultural settings, constitutes complex interactions of interconnected factors, including workers' health and safety, pesticide hazards reduction, pollution reduction, and seeding accuracy, which are often overlooked (Mahroof et al., 2021; Adebivi and Olabisi, 2022). Hence, using a conceptual model that precisely captures key agricultural challenges is essential for this research, as overcoming these challenges may determine and influence stakeholders' uptake of I5.0 drones. Moreover, previous research (Alamgir Hossain and Quaddus, 2011) found that farmers' adoption of radio-frequency identification technology was influenced by the industry readiness of the technology, thus indicating that the adoption of technology in agriculture is also contingent on its wider adoption across the sector.

Introducing technology to agricultural practices presents numerous opportunities for change, innovations and economic

Volume 29 · Number 3 · 2024 · 468–496

development. However, stakeholders' intention to these technologies are encumbered by several factors. Traditionally, the adoption of technology within agriculture is associated with personal endowments, uncertainty, availability of inputs and infrastructures (Uaiene and Arndt, 2009). More recently, an aspect of literature has focused on learning and social networks as factors that determine technology adoption. Other research classed these elements into distinctive categories. For instance, Akudugu and Dadzie (2012) organised the determining aspects of agricultural technology adoption into three social, institutional and economic elements.

Features of the technology are crucial requirements, influencing stakeholders' perception of adopted technology. For instance, in a study exploring the determinants to consider adopting climate-smart agriculture (CSA), it was found that age, sex and education among other factors influence the adoption of CSA technologies (Sisay *et al.*, 2023). The findings reveal that stakeholders' intention to technology adoption were influenced when they perceived it to suit their needs. Jiang *et al.* (2023) also outline the adoption of low-carbon agricultural technologies was contingent on targeted incentives and purchasing subsidies, technical guidance and agricultural cooperative services. Yet, more studies are needed to understand adoption of I5.0 drones among food supply chain stakeholders.

2.2 Industry 5.0 and agriculture sector

Despite the advancements of I4.0, with studies outlining its potential to achieve higher sustainable supply chain performance (Belhadi et al., 2022), over time, the application of I4.0 has mainly been for profit maximisation, thus leading to the depletion of natural resources, negative consequences on the environment, and inappropriate work conditions - all of which subsequently caused unsustainable consumption pattern environmentally, economically and even socially (Bonilla et al., 2018). Therefore, it is argued that I4.0 still entails a huge cost to the environment (Oláh et al., 2020). Such concerns have triggered the evolution of I4.0 to I5.0, a terminology first coined by the European Commission (EC, 2021). Complementing the paradigm of the existing I4.0, I5.0 emphasises on the research and innovation as the elements driving the economy transition to a more sustainable economy, prioritising on delivering value to the stakeholders rather than solely to the shareholders.

The trajectory witnesses higher commitment on safeguarding the environment as well as the well-being of the workers (Ivanov, 2021a). Ivanov (2023, p. 1688) recently characterised I5.0 as a technological-organisational framework, by proposing that I5.0 is underpinned by the major technological principles of "collaboration, coordination, communication, automation, data analytics processing, and identification" covering four areas of organisation, management, technology and performance assessment across societal, network and plant (field) levels, framing a new triple bottom line as resilient value creation, human well-being and sustainable society, which spans the dimensions of planet, people and profit (see framework of I5.0 in Figure 1). The framework conceptualises that in the context of society, I5.0 constructs networks that enable the provision of products and services during crisis periods, a perspective which is

complemented by the human-centric contextualisation of ecosystems such as food and agriculture, for sustainable production and usage of resources. Meanwhile, at the network level, supply chain capabilities are designed to stay resilience and sustainable through lean management, such as redundancy avoidance and risk mitigation, calling for the network resilience to be considered from a value-creation perspective (Aldrighetti *et al.*, 2021; Ivanov, 2021a).

In food supply chains, variations in production, prices, weather and workers' health are huge risks that threaten the supply chain network integrity (Mahroof et al., 2021). Thus, agile, flexible and reconfigurable supply chains are required as they are sustainable and resilient (Shekarian et al., 2020). For instance, drainage water management or water gates systems are efficient in protecting farms against flood, but the benefit of investing in them can only be gained if the flood happens. Therefore, from a value creation perspective, these interventions are inefficient. Instead, the use of drones that connect to cloud computing to collect and analyse weather data and send alert to farmers if risks are detected is more valuable. At the plant (field) level, a human-centric perspective is adopted for the creation of an inclusive work environment, which is done through integrating AI into operation and creating health protection protocols (Shen et al., 2021; Sodhi et al., 2021).

Echoing the European Commission's (2021) vision of making workplaces more inclusive, building more resilient supply chains and adopting more sustainable ways of production, Choi (2021) suggests that I5.0 advocates the concept of "sustainable social welfare" through human-machine interactions. This contributes towards the sustainability of each plant (field) in the supply chain network, which eventually fortifies such network into a more resilient and sustainable network. To conclude, while a technology-centred approach drove the I4.0 (Ivanov *et al.*, 2021b; Zheng *et al.*, 2021), I5.0 focuses on value creation through technology use with resilience, sustainability and human-centricity as its key components (Ivanov, 2023).

In the context of agriculture and food supply chain, precision agriculture principles that underpinned agriculture 4.0 in the era of I4.0 helps farmers to enhance strategic and operational decision-making. The technology helps to tackle counterproductive activities such as excessive use of pesticides and seasonal seedings. The technology provides a systematic tool to detect unforeseen problems hard to notice by visual inspection on occasional checks or those that can only being detected through the accumulation of experience. Nonetheless, some challenges remain. These include a cleaner production and value optimisation towards the triple bottom line. On top of these, people and processes such as lack of awareness on the use of technology and sustainability, high cost of technology acquisition, economic of scales and digital divide have widened the challenge gaps.

The recent pandemic further inflicts labour shortage. I5.0 presents solutions to this issue, especially through I5.0 drones. The use of I5.0 drones, that distinguished by the interaction between human and technology for value creation, allows farmers to collect data and/or map their lands for problem detection, where solutions can be applied immediately to avoid problem escalation that may be more costly to manage. Thus,

more focus should be placed on understanding the humancentricity of I5.0 within the context of sustainable supply chains.

2.2.1 Transitioning from Industry 4.0 to Industry 5.0

In the context of agriculture, I4.0 focuses on the integration of advanced technologies such as robotics, AI and internet of things (IoT) to improve the efficiency and effectiveness of the entire agricultural value chain (Liu et al., 2020). These technologies have great potential in helping agricultural stakeholders make more informed decisions based on real-time data. A plethora of research has focused on precision agriculture (Liu et al., 2020; Meshram et al., 2022; Condran et al., 2022), where I4.0 technology is deployed for data collection on soil conditions, crop health and weather patterns using sensors, drones and satellite imaging. This information is then analysed to optimise irrigation, fertilisation and pesticide application, resulting in better resource utilisation and crop yields. Another popular focus is the "smart agricultural systems", where the I4.0 technology is advocated for farming process automation, such as planting, harvesting and monitoring. The proponents of this suggest that farmers may streamline operations, reduce labour requirements and enhance production by combining robotics and automation technologies with modern data analytics (Abbasi et al., 2022; Zhai et al., 2020).

Research has also focused on addressing supply chain disruptions with I4.0, through real-time monitoring and tracking technologies (Helo and Shamsuzzoha, 2020), data analytics (Seyedan and Mafakheri, 2020), traceability and transparency tools (Centobelli, 2022), assuring quality control

(Tsang *et al.*, 2019), eliminating waste (Dzhuguryan and Deja, 2021) and enabling more effective logistics (Sharma *et al.*, 2022). "Data-driven decision making" has also received significant attention from researchers, from the use of machine learning algorithms to assist farmers in better understanding patterns (Gardezi *et al.*, 2022), to predicting crop diseases (Chin *et al.*, 2023), through to optimising resource allocation and managing risks (Sharma *et al.*, 2020).

Nonetheless, there are various challenges that I4.0 agricultural-related research left unaddressed, particularly in terms of understanding human factors and their adoption intentions. With the emergence and rise of I5.0 technology, there is a shift in focus towards human-machine interaction for sustainability, ethical ways of working and value creation. The current state of I5.0 has resulted in a paucity of research pertaining to its application in the agricultural domain and to enhance supply-chain value.

Moreover. Ferreira *et al.* (2022) suggested that the majority of studies do not explicitly address the paradigm of I5.0 and there has not been much analysis on the application of I5.0 in the extant literature. Although focus was placed on addressing innovation and environmental sustainability challenges related to farming practices, discussions on factors facilitating the adoption of I5.0 technologies have hardly surfaced (Pallagst *et al.*, 2019; Sodano, 2019; Holroyd, 2022).

Given that I5.0 shifts the attention from shareholder to stakeholder value (Nahavandi, 2019), researchers (Chin, 2021; Colla *et al.*, 2021) have highlighted the significance of

Kamran Mahroof et al.

understanding the value of human intelligence before placing the cognitive and technical capabilities in manufacturing operations. Despite these calls, there is a paucity of I5.0 research which has empirically addressed human-technology interaction as a system, thus demonstrating the need for more research (Panagou *et al.*, 2023).

2.2.2 Industry 5.0 and human-centricity

Despite drones being one of the most intensively studied technologies in logistics in recent years (Kirschstein, 2020), the focus has largely been from technical perspectives, in terms of precision agricultural applications (Condran *et al.*, 2022), three-dimensional-mapping approaches (Jimenez-Brenes *et al.*, 2017), thermal imaging (Khaliq *et al.*, 2019) and remote phenotyping (Han *et al.*, 2021) as well as crop management. While studies have explored it from applied perspectives, such as its potential for last-mile deliveries (Kirschstein, 2020), less studies have focused on the application of drones from within the emerging paradigm of I5.0 and its adoption by operational workers. With the advent and proliferation of I5.0 and given the focus has previously been from technical lenses, there is a gap in addressing and understanding the adoption of such technologies from a human perspective.

Through examining the role of I5.0 for better food security, Guruswamy *et al.* (2022) outline that agriculture is set to become the second-largest user sector of I5.0 drones in the coming years. Thus, highlighting the significance of understanding the adoption and intention to use such innovative solutions by agricultural stakeholders. Zizic *et al.* (2022) argue that while I4.0 was based on the concept of smart factory and cyber-physical production systems, I5.0 has extended the social and environmental dimensions by focusing on the workers' skills, knowledge and abilities to cooperate with machines and robots, hence making it imperative that research is tailored towards understanding the intention to use I5.0 tools by workers.

Researchers (Grabowska et al., 2022; Longo et al., 2017; Ivanov, 2023) have called for better humanisation and sustainability of I4.0 and argue the need to redress the balance between human and machines, by placing the role of humans central to discussions of future industrial development, such as I5.0. For instance, Grabowska et al. (2022) outline a drawback of the extant I4.0 literature is that the role of current workers is very rarely mentioned and given that I5.0 involves returning the human factor to industry, through a combination of automaton alongside humans' cognitive skills and critical thinking (Longo et al., 2017), it makes it even more critical to look at human factors. Ivanov (2023) also argues that I5.0 cuts across a multitude of key concepts, namely, sustainability, humancentricity and resilience and that the contextualisation of the human-oriented and society-oriented aspects within I5.0 is a nascent area, worthy of academic attention and focus.

A review of the extant I5.0 literature indicates the importance of integrating I5.0 technologies within organisations supply chains (Cillo *et al.*, 2022; Xu *et al.*, 2021). Contrary to I4.0, the significance of human involvement within the I5.0 paradigm should be appreciated and further explored in academic research (Maddikunta *et al.*, 2022). According, the research addresses this void, by drawing attention to the role of humans within I5.0 advancements. The proposed research also Volume 29 · Number 3 · 2024 · 468–496

responds to Karmaker *et al.* (2023) call to conduct research into the adoption of I5.0 tools within emerging economy contexts. The authors argue implementing I5.0 applications to manage supply chain sustainability is easier for developed countries than emerging economies, therefore, outlining the opportunities and barriers to its adoption within emerging economies is important.

2.3 Theoretical background and conceptual model

While a plethora of studies have explored the role of innovative solutions in driving sustainable supply chains, limited focus has been placed on the role of drones in achieving this through cleaner agricultural production. However, by taking an interpretive structural modelling (ISM) approach, Mahroof *et al.* (2021) offer a robust model which uncovers 12 challenges which impede sustainable supply chains. Their study reveals the potential role of drones in overcoming these challenges, which, in turn, may assist organisations in transitioning towards sustainable supply chains. Given that the Mahroof *et al.* (2021) sustainability model outlines specific barriers and potential solutions to attaining sustainable supply chains, makes it a highly appropriate model for the purposes of the current study.

While their exploratory study derives insights through Circular Economy and Agritech literature, as well as expert opinions, the authors called for researchers to validate their parsimonious model in the future, as it is yet to be tested through empirical research. As such, this study aims to respond to this call by validating the model while investigating the propositions put forward in their research.

Extending research by empirically validating ISM analysis is a robust and appropriate approach. As highlighted by Singh and Rathi (2021), who state that a hybrid approach consisting of interpretive structural modelling-structural equation modelling (ISM-SEM) analysis offers significant insights, through firstly the ability to conceptualise and classify barriers according to their degree of influence and secondly by allowing for the validation of a relational structural model. In the context of this research, the ISM findings from Mahroof *et al.* (2021) will be used as a basis to further explore and validate the role of I5.0 drones in achieving sustainability in supply chains, while also validating factors which influence its uptake among agricultural stakeholders.

Moreover, unproductive workers and PHs are identified as key drivers of agricultural challenges by Mahroof et al. (2021). Accordingly, this study adapts the sustainability model and aims to validate the model through further empirical research. The framework (Figure 2) is an adaption of the unvalidated Mahroof et al. (2021) model, which is adjusted for the context of our paper, in which the aim is to evaluate the determinants of I5.0 drones' adoption among food supply chain stakeholders in Nigeria. The augmented conceptual model is presented in Figure 2, and we discuss the relationship between these variables in the sections below. As the research model proposed by Mahroof et al. (2021) is based on the data collected from the experts largely from the agriculture and technology domains for drone as a service for promoting cleaner agricultural production and circular economy for ethical sustainable supply chain, it makes sense to validate the proposed model and its related propositions to explore and validate this further with the primary data collected to evaluate food supply chain

Volume 29 · Number 3 · 2024 · 468–496

Figure 2 Drone adoption model

Source: Adapted from Mahroof et al. (2021)

stakeholders' intention to use I5.0 drones for cleaner production in food supply chains. By using the research model suggested by Mahroof *et al.* (2021), we are not only testing the strength of the model performing in the similar context but also enriching that model with the context-specific constructs such as seeding accuracy and drone application.

2.4 Hypotheses development

The sustainability model by Mahroof *et al.* (2021) argues for a hierarchical process in the adoption of a human-machine collaborative technology. Within this framework, pesticide hazard is considered an underlying challenge in farming operations. Thus, if adequately tackled could increase cleaner production in the agricultural supply chain. We adopt this framework in this study and identify the key driver for human-machine collaboration as pesticide hazard reduction, mediated by five variables: pollution reduction, plant diseases alleviation, seeding accuracy, workers' health and safety and related hypotheses presented.

2.4.1 The link between Industry 5.0 drones and pesticide hazard reduction

One of the major challenges of agricultural production is pesticide usage (Vasseghian et al., 2022). Several solutions have been developed to facilitate its application, such as using realtime detection systems, precise real-time treatment and unmanned drones to minimise hazards caused by pesticide use (Gonzalez-de-Santos et al., 2017). Researchers have argued for the use of emerging technologies such as AI, IoT, blockchain and digital twin to enhance automation and precise production systems (Rajput and Singh, 2020; Mubarik et al., 2021; Bag et al., 2021). As such, the agricultural sector is extensively using drones within its operations for aerial observations, sensing purposes, as well as spraying pesticides (Ayamga et al., 2021). Moreover, Liu et al. (2023a, 2023b) recently found that largescale agricultural producers in China preferred drone services for pesticide reduction. From an agricultural supply chain perspective, most emerging technology applications are still at the nascent stage and require further exploration.

While human expertise has been touted as pertinent in enhancing technological models, there are, however, limited studies on human-machine collaborative dynamics in enhancing the precise application of pesticide. The study places emphases on these dynamics for cleaner production, pesticide hazards reduction and increased agricultural efficiency. As such, if human expertise is used in conjunction with efficient and accurate drones, pesticide application would be enhanced, thus reducing hazards. It is therefore argued that I5.0 drones offer user-preferred manufacturing solutions; hence, the following hypothesis is put forward:

H1. The use of I5.0 drones will significantly reduce pesticide hazards.

2.4.2 The mediating links between pesticide hazards and stakeholders' intention to use Industry 5.0 drones

Agriculture production is negatively impacted by several issues, including plant pests and using pesticides is one of the most promising ways to tackle this issue (Rojas et al., 2022). The frequency and mode of using chemical pesticides have raised concerns for individuals and governments (Vasseghian et al., 2021). Although pesticides are frequently used to safeguard agricultural production and fulfil global food demand, they are also pervasive environmental pollutants (Alshahrani et al., 2021; Tang et al., 2021). As such, precise or reduced pesticide application may positively impact the environment. Diendéré et al. (2018) studied the interactions between stakeholders' beliefs relating to water pollution and pesticide use, revealing that they were less inclined to use pesticides when they understood the impact on water degradation. A recent study has shown that drone-assisted deliveries can reduce carbon emissions and overall costs (Meng et al., 2023). The sustainability model by Mahroof et al. (2021) suggests that addressing pesticide hazards will address the underlying agricultural supply chain issues, and thus, stakeholders may be inclined to use I5.0 drones. It implies that collaborative efforts of human expertise and machine accuracy, if used to mitigate hazards caused by using pesticides, may reduce pollution. This entails understanding when and how to precisely use drones for pesticide applications. As such, we propose that:

H2. Pesticide hazard reduction using I5.0 drones significantly influences pollution reduction for cleaner production.

Davidson et al. (2022) outline that precision agriculture has provided greater access to data for farmers and that aerial crop imagery can assist in estimating vegetation indices and boosting efficiency. Perz and Wronowski (2019) relate how aerial measurements can assist in increasing yields and improving the condition and efficiency of farms. Similarly, Mendoza et al. (2021) posit how data collected through drones allows farmers to optimize their use of water or chemicals to boost yield, which ultimately will help increase their net profit. Jensen et al. (2021) also reveal the predictive power of regression models trained on drone imagery, used within fields to predict infestations of annual grass weeds in the late growth stages of cereals. In addition, Herrmann et al. (2020) highlight how drones allow farmers to accurately predict yield. Spectral models can also differentiate between development stages and irrigation treatments, thus emphasising the predictive abilities to use drones in agricultural settings. Thus, the following hypothesis is put forward:

H3. The application of pesticides through precision I5.0 drones will increase prediction accuracy.

The relationship between pesticide hazard reduction and plant diseases has been established in the literature. It depicts that plant disease will be eliminated if pesticide hazards are curbed and that by automating the plant disease detection process, losses in yield can be prevented (Chin et al., 2023). Many studies have examined the potential of I4.0 applications in minimising plant diseases or their earlier detection (Khattab et al., 2019). Similarly, Stella et al. (2017) highlights the importance of such applications to optimise pesticides, particularly for the future of farming practices. Khanal et al. (2017) used hyperspectral sensing to monitor crop stresses, diseases and irrigation stress. Although studies have examined how diseases and crop health can be monitored through sensory techniques (Spalevic et al., 2018), drones have unlocked even more opportunities for plant disease management (Mahroof et al., 2021). A thorough understanding of the plant, the surrounding conditions and the common illnesses or other issues that the plant is prone to is pertinent in plant disease management. A false diagnosis might result in the overuse of pesticides, a waste of resources in terms of time and money and a plant's ongoing deterioration if such information is not provided. Therefore, it is argued that collaborative human-machine expertise in plant disease management would contribute to precise application of pesticide hazard which, in turn, mitigate plant disease. As such it is proposed that:

H4. The effective and precise application of pesticides using I5.0 drones will significantly impact plant disease.

According to Huang *et al.* (2021), having a higher awareness of the harms of pesticides to the ecological environment lowers the possibility of its overuse. Thus, when guiding farmers to use new agricultural technologies, disseminating information to those who have adopted such technologies is imperative (Gao *et al.*, 2020). The application of pesticides not only assists in

Volume 29 · Number 3 · 2024 · 468–496

eradicating harmful microorganisms but it can also be counterproductive, killing beneficial microorganisms and vertebrates, thus disrupting the seeding process (Liu *et al.*, 2023a, 2023b). As well as causing ecological damage, pesticides have been shown to negatively impact sales and quality of yields (Xie *et al.*, 2019). Hence, the utilisation of precision treatment to overcome the disease of plants, thus impacting revenues raised through the cultivation of plants and crops, may influence stakeholders' intention to use precision technologies. Moreover, the spraying capabilities of drones can offer precision agricultural solutions, from precision use of pesticides through to accurate aerial seeding (Liu *et al.*, 2023a, 2023b). Therefore, the following hypothesis is put forward:

H5. The application of pesticides through precision I5.0 drones will increase seeding accuracy.

Although pesticides contribute to food security, they are considered detrimental to workers health and are to blame for acute illnesses in populations (Ngowi et al., 2016). Pesticide issues on workers are generally due to incorrect and poor application of pesticides (Kumar et al., 2014). Xu et al. (2021) discusses the potential of I5.0 through augmenting human values and approach in building resilient manufacturing systems and supply chains. The emphasis is on human-robot collaboration where human and machines can work together to optimise systems operations (Leng et al., 2021). It extends beyond programming the drones for pesticides use on farmlands to understand areas where health and safety may be breached. It requires the intervention of human expertise. Moreover, studies highlight the role of drones in reducing health and safety challenges. For instance, Roldán-Gómez et al. (2021) found that drone swarms can be used to improve firefighters' efficiency and their safety. Conversely, in the context of farming operations, if workers use I5.0 drones to enhance the precision application of pesticides, their health and safety challenges may also be minimised. Therefore, the use of I5.0 drones may reduce pesticide hazards and, in turn, mitigate workers health and safety challenges. Accordingly, the following hypothesis is put forward:

H6. The precise application of pesticides hazards using I5.0 drones will reduce workers' health and safety challenges.

It is reported that farmers exposed to a large quantity of information on agriculture safety and agricultural pollution can induce emotional resonance and crisis awareness, stimulate their sense of responsibility and form awareness of green production (Kansiime et al., 2019). Moreover, studies have shown that pesticide application and fertiliser technologies affect stakeholders' production and investment behaviours. According to Zhao et al. (2020), stakeholders' awareness of food safety and agricultural pollution can ultimately impact and change their agricultural practices. In adopting the framework set out by Mahroof et al. (2021), it can be argued that pesticide hazard reduction may act as a mediator between pollution reduction and stakeholders' intention to use I5.0 drones. It demonstrates that if precision pesticide application can accurately reduce pollution, then stakeholders in the agricultural supply chain would be more inclined to use I5.0 drones. Thus, the following hypothesis is put forward:

H7. Pollution reduction through increased precise pesticide application increases stakeholders' intention to use I5.0.

Research reported that the motivation to adopt new technology is heavily influenced by its perceived usefulness and perceived ease of use (Ali et al., 2021a, 2021b). Agricultural stakeholders who lack an understanding of I5.0 technology will be less likely to adopt the technology, despite its usefulness. Tang et al. (2021) outline the use of pesticides conflicts with UN Sustainable Development Goals (e.g. SDG3, good health; SDG6, clean water; SDG15, protection of life on land) and contributes to the loss of biodiversity (Singh et al., 2023). In spite of these negative connotations, Strange et al. (2022) argue that pesticide use is expected to increase to help attain food security (SDG2), in response to the global food crisis. Drone precision in agriculture is not only able to reduce the use of pesticides but also has the potential to increase yields, through healthier crops and cost optimisation (Mahroof et al., 2021). A lack of accurate yield forecasts can lead to inefficient allocation of resources, such as labour, tools as well as transportation. However, machine learning through I5.0 drones equipped with (red, green, blue) cameras can assist in offering more precise vield predictions (Chen et al., 2019). Ali et al. (2021a, 2021b) also highlight the ability of drones to expedite agricultural processes, while being accurate and cost-efficient, can garner interest in its adoption. Therefore, we argue that:

H8. The significant increase in prediction accuracy through efficient and precise pesticide application will increase stakeholders' intention to use I5.0.

Plant diseases have adverse effects on both the quantity and quality of agricultural products, posing a threat to food safety (Hofmann et al., 2023). These harmful impacts lead to financial losses in crucial production sectors that are especially consequential for emerging economies, as the manual examination by specialised experts is not only time-consuming but also costly (Chin et al., 2023). Consequently, automating plant disease detection such as blight and fungus using colourinfrared images, and applying treatment based on machine learning algorithms through the use of drones appears as a viable method to mitigate yield loss risks effectively (Devi and Priya, 2021; Sinha, 2020). Moreover, Liu et al. (2018) also found that agricultural actors are likely to adopt new practices if it leads to increased profits. The precise treatment of plant diseases leads to increased and healthier yield, thus leading to profitability. Therefore, we therefore propose that:

H9. Precision treatment of plant disease using I5.0 drones facilitates stakeholders' intention to adopt the new technology.

Zuo *et al.* (2021) found that tangible benefits can assist with the uptake of drones in farming operations. Mohan *et al.* (2021) reveal spraying mechanisms on drones can offer practical and tangible benefits to yield, by helping initial vegetation growth periods. Moreover, Yawson and Frimpong-Wiafe (2018) highlighted how aerial data captured from drones can assist crop inventories conduction and yield estimates. A plethora of studies have also outlined the role of drones in accurately facilitating seeding processes within agricultural settings. For

Volume 29 · Number 3 · 2024 · 468–496

instance, Wang *et al.* (2022) posit how drones can successfully and stably plant seeds into the soil through sow seed capsules, while Liu *et al.* (2023a, 2023b) outline how modern drones have the capability to fire seeds into the soil for plantation purposes. Therefore, drones, along with image processing, can optimise management and assist with breeding purposes (Gnädinger and Schmidhalter, 2017). Accordingly, the following hypothesis is put forward:

H10. Seeding accuracy facilitated by precise drone application increases stakeholders' intention to use I5.0 drones.

The agricultural sustainability model by Mahroof et al. (2021) also highlights the link between workers' health and safety challenges and stakeholders' intention to use I5.0 drones as hierarchical. The debate here is that if the challenges workers face while executing farming operations are adequately addressed using I5.0 drones, then the intention to use this technology may increase. It stems from the role of drones being perceptive and informed about workers' desires and aiding in the decision-making process to address them (Nahavandi, 2019). Several studies have examined the role of I4.0 in tackling workers' health and safety challenges (Trivelli et al., 2019; Bernhardt et al., 2021). However, these studies consider combining manual and automotive processes in addressing challenges. It depicts the absence of trust when using autonomous technology. In this study, we argue that the collaborative relationship between humans and machines through I5.0 drones would increase farming operations efficiency, including tackling workers' challenges, especially pesticide hazards. It, in turn, will motivate stakeholders in their intention to use I5.0 drones. Hence, the following hypothesis is put forward:

H11. Workers' health and safety increases agricultural stakeholders' intention to use I5.0 drone.

3. Research methods

Dora *et al.* (2020) outline the need for more studies to evaluate the interaction between different stakeholders in the food chain, including upstream stakeholders, such as farmers. As such, this study aimed to examine the determinants of I5.0 drones' adoption in the food supply chain in Nigeria using a sustainability model for cleaner production. Data was gathered using survey questionnaires administered in English to achieve the research objectives. All items of the constructs were measured using a seven-point Likert scale with "1" indicating "strongly disagree" and "7" indicating "strongly agree". The questionnaire was divided into two parts.

3.1 Developing constructs

The constructs used in this study were generated from existing literature and in line with the Mahroof *et al.* (2021) framework. Eight constructs were adopted from Silva *et al.* (2011), Tey and Brindal (2012) and Barnes *et al.* (2019) to measure precision agricultural techniques, in this case, drone application. The responses included "Drones will lead to lower environmental impact" "Drones will lead to a higher yield". Constructs were adapted from Lithourgidis *et al.* (2016) to measure precise and

effective pesticide application on a three-item scale. Sample items included "I believe pesticides affect the environment" and "I use the product with the frequency indicated on the label".

Items taken from Bagheri et al. (2019) were used to measure plant disease reduction. Sample items included "I use chemical as well as non-chemical methods to reverse crop disease" and "The current methods used are effective in protecting crops". Workers' health and safety challenges were also a construct used to measure stakeholders' intention towards adopting I5.0 drones. Thus, lower workers' health and safety challenges drones' application compatibility increased through stakeholders' intention. A five-item scale adapted from Roman-Muniz et al. (2006) and Lunner-Kolstrup and Ssali (2016) measured workers' health and safety. The cross-loadings and Cronbach item values suggested the elimination of variables. In this study, a two-item scale was used. The sample items included "I have experienced skin-related problems (such as rash, itching, discolouration) from work during the past 12 months" and "I have experienced skin-related problems (such as rash, itching, discolouration) from work during the past 12 months".

Precision and effective pesticide application has also been suggested to increase prediction accuracy (PA). A four-item scale from Liu and Huang (2013) was used to measure the predictions accuracy construct. The items included "if I spray less, my income will be reduced", "if I use pesticides, this leads me to a favourable result, i.e., increased production" and "if I use pesticide spraying, my farm revenue will sustain".

PR was also a defining construct in measuring drone compatibility and stakeholders' intention to use. A five-item scale adapted from Pan *et al.* (2016) was used to measure pollution reduction. Three of these items were dropped due to failure to meet the required Cronbach and average variance extracted (AVE) 0.60 thresholds. The sample items were "My farming methods will not harm the environment" and "I am willing to treat pollution". Thus, the effective use of drones through efficient pesticide application will reduce pollution. To measure stakeholders' intention to use I5.0 drones, an eightitem scale was adopted from Yamano *et al.* (2015) and Bagheri *et al.* (2019). The items were measured on a five-point Likert scale, where one indicated "strongly disagree" and five "strongly agree". A summary of our constructs' development is presented in Appendix 1.

3.2 Data collection

The empirical context of this study is Nigeria's food supply chain due to the prominent level of agricultural activities in the country and its classification as a developing economy (The World Bank, 2022). Our unit of analysis was focal firms, where each participant represented a single firm in the supply chain. It was essential that the participants were knowledgeable on the decision-making processes of their firms, and as such, the views provided were representative of their focal firms. A questionnaire administered through a Web-link survey was used to collect data from participant. We piloted the questionnaire with 15 food supply chain experts and seven academics to ensure the clarity of all measurement items. All identified issues, including ambiguity, wording and formatting, were addressed before administering the questionnaire *Volume 29 · Number 3 · 2024 · 468–496*

(Saunders *et al.*, 2019). For instance, I5.0 drones was used instead of unmanned aerial vehicles (UAVs), and pollution reduction replaced sustainable practices.

3.2.1 Population, sampling techniques and response rate

Since the aim of our study was to evaluate the intention to use I5.0 drones for sustainable farming operations, it was pertinent that respondents in charge of the decision-making process and who understood the phenomenon under study completed the questionnaire. As such, we considered the non-probability sampling technique (snowballing and purposive) as suitable (Saunders, 2019). It implied that anybody identified as knowledgeable about the researched phenomena was approached to complete the survey.

We approached 950 stakeholders of managerial positions involved in various activities in the food supply chain around Nigeria with particular emphasis on the decision-making processes. The questionnaire was circulated via a Web survey link in an e-mail. Detailed information on the purpose of the study, confidentiality information and a consent form was attached to the questionnaire sent through their e-mails. To facilitate recruitment, a multi-channel strategy was used through industry connections and professional groups. E-mails were sent fortnightly as reminders to prompt questionnaire completion.

The data were collected between January and March 2021. A total of 270 responses were completed and returned. However, 264 were considered valid, indicating a response rate of 27.7%. A response rate between 6% and 16% is considered valid (Dillman, 2011). Similarly, the total number of valid responses is appropriate for the partial least squares structural equation modelling (PLS-SEM). Since each respondent represented single firms, the possibility of common method biased (CMB) may occur (Podsakoff *et al.*, 2003). We used the Harman's test to check (Harman, 1976). The results demonstrate the absence of CMB with a cumulative average variance of 25.51%.

3.3 Sample characteristics

We used a sample of 264 stakeholders in the food supply chain in Nigeria to achieve our research objectives. A summary is presented in Table 1. The summary shows that most of the stakeholders in our sample were male with over ten years of experience in perishable food supply chain farming. A crosstabulation between age and type of supply chain showed that most respondents above 35 years engaged in perishable foods and grains supply chain more than any other age group. Also, stakeholders above the age of 36 had more positive towards the use of I5.0 drones in agricultural operations.

3.4 Data analysis

3.4.1 Model measurement assessment

We examined the constructs of our measurement model using item loadings and composite reliability, discriminant validity (AVE) and convergent validity. As presented in Table 2, the findings establish construct reliability as all the outer loadings, the overall Cronbach alpha score and composite reliability stood above the recommended 0.60 (Bland and Altman, 1997; Hair *et al.*, 2017; Vaske *et al.*, 2017). The values for the convergent validity were also above the recommended 0.50

	All of the above	2	0.8
Source: Authors' (2023)			

threshold, which suggests that the model used in this study to measure was a good fit.

3.4.2 Discriminant validity tests

The discriminant validity was considered using the Fornell–Larcker criterion (1972) to assess the model parameters. To measure this, the square root of a construct's AVE should be lower than its highest correlation. The findings are presented in Table 3.

3.4.3 Quality of model

The structural model quality was examined using the R^2 and the Q^2 by Geisser (1974) model measurements as presented in Table 4. Pollution reduction (PR) was measured by two constructs and had significant R^2 and Q^2 (0.436 and 0.418). Plant disease (PD) was measured using five constructs with R^2 and Q^2 (0.324 and 0.206).

4. Findings

We analysed the data using partial least square structural equation models (PLS-SEM). The PLS-SEM was used to provide a predictive approach to handle complex models where no prior assumptions have been considered (Hair *et al.*, 2019; Sarstedt *et al.*, 2020; Dash and Paul, 2021). In this case, our complex model involves six drivers and challenges of sustainability technology adoption. Presented in Figure 3 are the standardised estimates from the structural equation modelling (SEM). The results of the hypotheses are presented in Table 5. Firstly, our findings confirmed that the use of I5.0 drones increased the effectiveness and precision application of pesticides supporting H1 ($\beta = 0.302$, p > 0.000). We found that effective pesticide application using I5.0 drones had a positive and significant effect on PA ($\beta = 0.327$, p > 0.000), SA ($\beta = 0.459$, p > 0.000), PD ($\beta = 0.590$, p > 0.000) and PR

 $(\beta = 0.238, p > 0.000)$. The findings also indicated a positive and statistically significant relationship between PH and WHS $(\beta = 0.301; p > 0.000)$, denoting the support for *H2–H6*. We found statistically insignificant relationships between SHA and PR, PA, SA and WHS. Hence, *H7*, *H8*, *H10* and *H11* were not supported. A positive and statistically significant link between PD and SHA ($\beta = 0.127, p > 0.005$) supports *H9*. The findings indicate that although reduced pesticide hazards mitigated sustainability challenges, they did not influence stakeholders' intention to adopt I5.0 drones. A summary of the hypothesis tested is presented in Table 5. A summary of the structural path analysis is presented in Appendix 2.

The indirect effect of I5.0 drones and sustainability challenges indicate positive and statistically significant relationships, as presented in Table 6. It implies that I5.0 drones have the capacity to also directly address sustainability issues of farming operations.

The specific structural path to increase stakeholders' intention towards the I5.0 application was analysed. We found the path for *Drones' applications Pesticide hazard* \rightarrow *Plant diseases* \rightarrow *Stakeholders' intention to use* statistically significant ($\beta = 0.021$, p < 0.10). Thus, stakeholders' intention towards I5.0 drones is largely influenced by efficient and precise pesticide application and plant disease reduction. We also found the DA \rightarrow PH \rightarrow WHS path statistically significant ($\beta = 0.091$, p < 0.01) 0.005). It implies that drone applications will reduce workers' health and safety through pesticide hazard reduction.

PLS-SEM, a variance-based structural equation modelling, was used to test the model. Analysis was calculated using complete Bootstrapping with 5,000 replications.

In Table 7, we present the results of the performance map analysis. This analysis aims to rank factors that influence stakeholders' intention to adopt I5.0 drones. Our findings

rank predictions accuracy as the most critical factor, followed by I5.0 drone application, pesticide hazard, and plant diseases. We find pollution, seed accuracy, and workers' health and safety the least factors influencing stakeholders' adoption of I5.0 drones. These are in line with our hypothesis testing (Table 8).

5. Discussions on the adoption of Industry 5.0 drones for cleaner food production

Our findings advocate for the use of I5.0 in increasing agricultural operational performance and environmental sustainability by reducing plant diseases. However, we found

that while I5.0 does reduce health and safety challenges, this was not an influencing factor for the uptake of I5.0 by supply chain stakeholders. The logical explanation suggests that emerging technologies such as I5.0 are squarely focused on improving operations processes with less focus on people in operations:

Figure 3 Structural path model

RQ1. What factors influence food supply chain stakeholders to adopt I5.0 drones for cleaner production?

In this study, we were concerned with the factors that propelled food supply chain stakeholders to use I5.0 drones for cleaner production. With the use of an augmented parsimonious model developed by Mahroof *et al.* (2021), our findings highlight factors that influence I5.0 adoption and their implications. Firstly, the analysed data showed a positive and statistically significant relationship between pesticide hazard reduction and the use of I5.0 drones. A reduction in pesticide hazards, in turn, reduced plant diseases and increased prediction and seeding accuracy. It, therefore, suggests a hierarchical link between I5.0 drones and food production operations where stakeholders' intention to adopt I5.0 technology begins with the contribution of drone use to pesticide hazard reduction.

We also found that stakeholders were not necessarily concerned with pollution reduction and, as such, may not be motivated to adopt I5.0 technologies to address these issues. It highlights stakeholders' environmental behaviour and the poor

understanding of factors capable of mitigating pollution in an emerging economy like Nigeria. However, some studies have suggested that understanding identities, behavioural beliefs; agency; networks and relationships; and social norms may propel farmers' intention to pollution reduction through precise application (Wang *et al.*, 2019). Notwithstanding, policies need to be in place to educate farmers on environmental behaviours. Therefore, our analysis reveals pollution reduction through increased precise pesticide application does not increase farmers' intention to use I5.0.

However, although food supply chain stakeholders are more concerned about the precise application (pesticide hazard reduction, seeding accuracy) of drones in agricultural operations, these activities invariably enhance cleaner production. As such, we provide empirical evidence to support the contributions of I5.0 in cleaner production. It is particularly relevant as over 16% of climate change issues have been attributed to land degradation caused by pesticide application (Pinguet, 2020). Through precise application the land is preserved without excesses encroaching on the environment and plant diseases are curbed (Khattab et al., 2019). Thus, a reduction of pesticide hazards through precise application positively impacts the environment (Balafoutis et al., 2017). These findings are in consonance with the study of Sharma and Arya (2022), who found that the use of I5.0 UAV contributed to improving air quality.

Further, the findings also indicated that the absence of a relationship between stakeholders' intention to adopting I5.0 drones and workers' health and safety challenges. It implied that although stakeholders considered I5.0 drones beneficial to farm operations, they were less inclined to adopt drone use if

Table 7 Hypothesis testing

No	Hypothesis	Findings
H1	The use of I5.0 drones will significantly reduce pesticide hazards	Supported
H2	Pesticide hazard reduction using I5.0 drones significantly influences pollution reduction for cleaner production	Supported
H3	The application of pesticides through precision I5.0 drones will increase prediction accuracy	Supported
H4	The effective and precise application of pesticides using I5.0 drones will significantly impact plant disease	Supported
H5	The application of pesticides through precision I5.0 drones will increase seeding accuracy	Supported
H6	The precise application of pesticides hazards using I5.0 drones will reduce workers' health and safety challenges	Supported
H7	Pollution reduction through increased precise pesticide application increase stakeholders' intention to use 15.0	Not supported
H8	The significant increase in prediction accuracy through efficient and precise pesticide application will increase stakeholders' intention to use I5.0	Not supported
H9	Precision treatment of plant disease using I5.0 drones facilitates stakeholders' intention to adopt the new technology	Supported

the specific purpose was to address workers health and safety challenges. It supports existing literature of stakeholders' concern about workers' health and safety challenges. For instance, Lotfi *et al.* (2021) found that workers' safety is often neglected in supply efficiency. Alsamawi *et al.* (2017) also provided evidence of hidden workers' challenges along supply chains that have been overlooked. However, I5.0 use tackles this challenge as it emphasises collaborative operations between robots and human (Ivanov, 2023). Due to the increased small footprint and adaptability of drones, I5.0 drones can be used to make working environments safe, thus addressing workers' health and safety challenges (Grobbelaar *et al.*, 2021):

RQ2. Does the adoption of I5.0 drones tackle food supply chain challenges?

Several challenges to production in the food supply chain have been identified to include pesticide hazard, pollution reduction, seeding accuracy, plant diseases, accurate prediction and workers' health and safety (Mahroof *et al.*, 2021). Our findings indicated I5.0 drones have the capacity to tackle these challenges and, in turn, support sustainable supply chain operations. For instance, we found that the use of I5.0 drones contributed to reducing pesticide hazards and plant diseases. It, in turn, enhances agriculture operations and food production. It implies that the use of I5.0 drones enhances agricultural production, facilitates the flow of produce in the supply chain by reducing hazards caused by pesticides and promotes cleaner production. The findings also indicate that I5.0 has the potential to reduce worker's health and safety, an issue which is extensively highlighted within agricultural research.

Thus, the precise application of pesticides reduces associated hazards such as pollution and plant diseases, which invariably have a ripple effect on other aspects of agricultural production. Our findings are in line with existing literature, which argues that I5.0 enhances production systems (Bag *et al.*, 2021). In this case, food production, which could help alleviate issues with food shortages. For instance, Liaghat and Balasundram (2010) and Wang *et al.* (2018) showed that the use of drones improved crop yield through precise application of pesticides. Similarly, Guruswamy *et al.* (2022) showed that the vulnerability of food systems can be mitigated using I5.0 drones.

5.1 Theoretical implications

For researchers interested in gaining valuable insights into the understanding of I5.0 drones use for cleaner agricultural *Volume 29 · Number 3 · 2024 · 468–496*

production, this study and its findings offer several theoretical implications. The first substantial contribution is that it is one of the first studies to adapt and test the proposed sustainability model by Mahroof *et al.* (2021). It does this by demonstrating the various stages influencing stakeholders' intention to use I5.0 drones. Previous research (Bag *et al.*, 2021; Kumar *et al.*, 2022) has not focused on the capacity of the human dimension in facilitating sustainable practices in farming operations.

In this regard, we showed that the intention to use industry I5.0 drones began from the collaborative ability to ensure precise application of pesticide for hazard reduction which, in turn, ensures seeding accuracy, pollution reduction, workers health and safety challenges and prediction accuracy. The research thus extends the human-AI discourse by validating the Mahroof *et al.* (2021) sustainability model and demonstrating the importance of drones in facilitating sustainable agriculture for food security. Hence, the study helps to provide insights into human factors within the paradigm of I5.0. Previous literature within the paradigm of I4.0 focused largely on the automation and technical aspects and overlooked human factors and those who were tasked with adopting the technology.

Industry experts and I5.0 drone operators have always believed that drones' ability to overcome a host of longstanding agricultural challenges naturally influences the stakeholders' intention towards drones, increasing the uptake of I5.0 drones in agriculture. This study tests whether I5.0 drone-led solutions to the existing, overarching agricultural challenges previously identified in a study by Mahroof et al. (2021) could influence the uptake of I5.0 drones by farmers in the context of an emerging economy. The novel contribution of this model is underpinned by its discovery that these solutions do not necessarily influence the stakeholders. Hence, not all solutions to agricultural challenges that can be solved by I5.0 drones directly influence the stakeholder's intention or motivation to adopt drones in their farming activities. This study reveals a statistically significant influence of factors determining the stakeholders' intention towards using I5.0 drones.

Unlike what was suggested in many studies, the only droneled solutions to agricultural challenges that will increase the stakeholders' drone adoption are linked to factors that affect yield generation. Stakeholders are prone to adopt drones in a situation where drone usage helps to enhance plant health, which, in turn, results in economical use of resources and increased crop production. The findings reveal that the ability to minimise plant disease is a critical factor in the adoption of I5.0 drones by agricultural stakeholders in this context, given severe constraints in production outputs resulting from poor crop quality, thus ultimately harming their yield.

Plant diseases have always been a tough challenge for agricultural stakeholders, especially when the extreme climate has already challenged the yield. These factors, their interrelationship, and criticality are mapped in Figure 3. The model suggests that environmental sustainability (i.e. environmental pollution), workers' health, prediction accuracy and safety are the stakeholders' most minor concerns, signposting the lack of awareness of those realms within this economic region, also alluding to the lack of planning undertaken by agricultural stakeholders. It is proposed that the same situation applies to the agricultural stakeholders in similar contexts of emerging

economy nations, where monetary incentives primarily drive actions – hence healthy crops, translating to increased yields, take priority over other outcomes regarding drone usage in agricultural activities.

The second main contribution of our findings is the negative link between pollution control and stakeholders' intention to use I5.0 drones. It contradicts existing studies which suggest that demonstrating the ability of a technology to reduce pollution in farming operations increases stakeholders' intention to use it (Wang *et al.*, 2019). It thus highlights that in developing economies, the intention to use a human-centric technology such as I5.0 drones is more focused on treating plant diseases though precise application of pesticides. Further studies should be carried out to provide possible explanations.

In addition, our model highlights that in developing economies, the study helps to provide insights into human factors within the paradigm of I5.0. Previous literature within the paradigm of I4.0 focused largely on the automation and technical aspects and overlooked human factors and those who were tasked with adopting the technology. Therefore, this research provides empirical insights into the human-centric perspective and contributes to a growing body of I5.0 literature and responds to the calls of Chin (2021), Colla et al. (2021) and Panagou et al. (2023), by placing focus on human-centricity and empirically exploring adoption of I5.0 through its human counterparts. Thus, I5.0 drones can improve sustainable agriculture through the practice of precision agriculture generated from real-time data of crop and soil moisture conditions. From the findings, we can infer that the data generated by I5.0 drones can inform decision-making such as planting schedules, precision pesticide application and pollution reduction. This can provide valuable guidance for sustainable farming practices and more resilient agri-supply chains.

Further, the empirical testing of the sustainability model demonstrates an approach to understanding how I5.0 drones can be used in ensuring sustainable operations in agricultural supply chain. However, the unsupported hypothesised relationships (Pollution reduction, seeding accuracy, prediction accuracy and workers health and safety challenges) may indicate the need to address other factors, including financial and cultural approach. As such, adapting the model to accommodate different economies may be beneficial.

5.2 Practical implications

This research explored supply chain stakeholders' intention to adopt 15.0 drones based on a sample of 264 farmers. A questionnaire developed from the extant literature was distributed across farms in Nigeria, with a majority of stakeholders highlighting their willingness to adopt the drones to minimise plant disease. However, to maximise the benefits of 15.0 drones, there is a need for more research and awareness of the benefits of such technologies while also educating farmers on health and safety, how it can assist in proactive planning and better prediction accuracy and in particular on the benefits of using 15.0 for precision pesticides, which can minimise pollution and other associated adverse effects resulting from its excessive use. These key factors were not seen as influencing factors for the stakeholders. Accordingly, the following recommendations are proposed:

Volume 29 · Number 3 · 2024 · 468–496

Firstly, there is a need for the Federal Ministry of Agriculture and Rural Development to commission further research about the economic and societal benefits for Nigeria associated with plant diseases across agricultural settings. This factor was seen to influence adoption intention. Yet, limited research has been conducted on the economic and ecological benefits resulting from reduced pollution (pesticides) and plant disease for Nigeria's agriculture production. Moreover, further evidence on the broader benefits of increased seeding accuracy and the impact of having better yield predictions would provide further impetus for adopting I5.0 drones among supply chain stakeholders. As this research has indicated these as influencing factors towards adopting I5.0 drones, more effort should be placed to understand how this can be operationalised within the farms.

Secondly, this research revealed that farmers were not interested in adopting I5.0 drones, despite acknowledging it may assist with health and safety-related challenges. Based on the findings, this can be attributed to the fact that the farmers fail to see the importance of health and safety and see economic benefits as a priority. Moreover, the findings also indicated that despite acknowledging the role of I5.0 drones in offering more precise and accurate pesticides application, farmers failed to acknowledge the connection between the precision application and personal health and safety. Thus, it is proposed that the Federal Ministry of Agriculture & Rural Development and other agricultural agencies disseminate factual evidence regarding the adverse health effects of pesticide exposure. The findings also suggest that the stakeholders appreciate the role of I5.0 drones in reducing pollution, yet this was insufficient in influencing their uptake of drones. Therefore, more information needs to be shared with farmers to be aware of the practical economic and societal benefits of reducing pollution.

Thirdly, many farmers in developing and emerging countries face technology and credit market inadequacies, leading to financial constraints when adopting new forms of technology. Hence, the government should bolster research and development spending across agriculture to offer training and make the uptake of I5.0 drones accessible and affordable to farmers. Handheld sprayers are one of the most common methods of applying pesticides and are considerably cheaper and require little to no training. In other words, without government support schemes and financial support, the uptake of such innovative solutions in the form of I5.0 will always be impractical and too costly to implement.

6. Conclusion, limitations and future research

Mendoza *et al.* (2021) have previously highlighted that the contradicting views and perspectives surrounding drones have slowed the rate of adoption and integration within public, governmental and commercial settings. Accordingly, this research set out to explore factors that influence the adoption of 15.0 drones among supply chain stakeholders from an emerging economy. In doing so, this research reveals the significance of using 15.0 drones for the precision treatment of plant disease as a critical factor in influencing the uptake of 15.0 drones among Nigerian supply chain stakeholders. Moreover, the research revealed how health and safety and pollution reduction were not influencing factors. These findings offer a potentially vital

precedent for agricultural stakeholders, such as farmers, policymakers and food producers in emerging economies pursuing smart farming and intelligent systems for agricultural operations. The findings from this research can inform food producers and policymakers of the opportunities and challenges of implementing I5.0 drones.

In conclusion, the agricultural practice requires technological advancement in all spheres of its operations. However, human capital remains crucial in introducing and adopting technology in this context. Nigeria remains Africa's most populous country, with 30% of its population engaged in agricultural-related activities (UNICEF, 2019). As mentioned earlier, there may be issues with technology adoption if the aspects of human capital development are neglected. Human capital has enormous potential in Nigeria; a careful integration of technology with due consideration of the human factor will be necessary for its advancement within this context.

Despite the valuable contributions resulting from this research, we must also acknowledge the limitations. Firstly, the sample size for this research was 264; thus, to validate the robustness of the results even further, this research should be replicated with a more significant and more representative sample.

In designing the sustainability model used in this study, we did not consider various variables, including perceived usefulness, perceived ease of use, trust, compatibility and other behavioural factors. As such, future studies should augment the model to include these variables. Moreover, while the purpose of the study was to explore drone adoption in Nigeria, many supply chain stakeholders in developing and emerging countries have limited exposure and awareness of drone technologies. It may have influenced their responses to the survey questions. Additionally, drone applications in agriculture are in their infancy, regardless of the economic status of countries. Therefore, to further validate the findings of this research, it is suggested that this research be conducted across other emerging economies and developed economies.

Appendix 1

 Table A1
 Defining constructs

Items	Description	Source
Drones' application		Silva <i>et al.</i> (2011), Tey and Brindal (2012),
DA1	IS 0 drange will load to lower environmental impacts	Barnes <i>et al.</i> (2019)
DAT	IS 0 drones will lead to iower environmental impacts	
DAZ	IS.0 drones will lead to significant management changes	
DA3	IS.0 drones will lead to improvements in crop quality	
DAG	15.0 drones will lead to a nigher yield	
DAS	15.0 drones will lead to lower production costs	
DAG	IS 0 drones will lead to a higher market share for the company	
DA7	15.0 drones will lead to compliance with regulations related to the domestic market	
	15.0 drones will lead to compliance with regulations related to the international market	V (2045)
Stakeholder's intention to use		Yamano <i>et al.</i> (2015)
FA1	I consider myself a progressive farmer	
FAZ	I like to try new agricultural technologies or practices	
FA3	l actively seek new information from others	
FA4	l like new ideas in general	
FA5	Other stakeholders think I am a progressive farmer	
FA6	Other stakeholders ask my opinions about agricultural technologies	
FA7	Other stakeholders will not object to how I produce rice on my fields	
FA10	l can adopt new agricultural technologies which are profitable	
Seeding accuracy		
SA1	Aerial seeding can accelerate seeding process	Diwate <i>et al.</i> (2018)
SA2	Using a helicopter or plane for aerial seeding is expensive	
SA3	Using a plane or helicopter for aerial seeding requires large amount of seeds	
SA4	Seeding is labour intensive	
SA5	Seeding process needs special skills	
Predictions accuracy		Liu and Huang (2013)
PA2	If my plants have become pest resistant, I still continue to use excessive amounts of pesticides	
PA3	If I spray less, my income will be reduced	
PA4	If I use pesticides, this leads me to a favourable result, i.e. increased production	
PA5	If I use pesticide spraying, my farm revenue will sustain	
Plant disease		Bagheri <i>et al.</i> (2019)
PD1	I believe pesticides are harmful to healthy crops (non-infested by pests)	
PD2	I believe pesticides residues contaminate crops	
PD3	I can recognise the most common plant disease in my farm	
PD4	I use chemical as well as non-chemical methods to reverse crop disease	
PD5	The current methods used are effective in protecting crops	
Pesticide hazard		Lithourgidis <i>et al.</i> (2016)
PH1	I apply the rates indicated on the product label	
PH2	I use the product with the frequency indicated on the label	
PH4	I believe pesticides affect the environment	
Pollution reduction		Pan <i>et al.</i> (2016)
PR1	My farming methods will not harm the environment	
PR2	I am willing to treat pollution	
Workers' health and safety		Roman-Muniz <i>et al.</i> (2006)
WHS2	I have experienced skin-related problems (such as rash, itching, discoloration) from work during the past 12 months	Lunner-Kolstrup and Ssali (2016)
WHS5	After pesticides and agrochemicals, I experience either one or more of the following symptoms; dizziness, vomiting, pain and a burning feeling in the face and eves after spraving	(20.0)

About the authors

Kamran Mahroof is an Associate Professor in Supply Chain Analytics and leads MSc Applied Artificial Intelligence and Data Analytics at the School of Management, University of Bradford. Prior to academia, Kamran held several industry roles within Logistics and Supply Chain, which helped shape his research interests. He actively researches studies in the areas of technology adoption and sustainable supply chains and regularly appears on national TV. As well as publishing in leading peer-reviewed journals, his research also features on reputable media outlets such as The World Economic Forum and The Conversation. Kamran is a fellow of the UK Higher Education Academy. Kamran Mahroof is the corresponding author and can be contacted at: k.mahroof@bradford.ac.uk

Amizan Omar is an Associate Professor in Strategic Management and Director of Accreditation at the School of Management, University of Bradford. Her passion for research is interdisciplinary in nature, focusing on the institutionalisation of digital technology in organisations and its interplay with institutional actors and structures in the context of public sector service transformation and their implication on tackling managerial and societal issues for sustainable societies. She has published over 30 scientific articles in leading peer-reviewed journals and conferences and been involved as a Co-investigator in multi-million-pound research projects funded by the European Commission (FP7 and H2020) and UK Local Government.

Emilia Vann Yaroson is a Lecturer in Operations and Analytics at the Huddersfield Business School, University of Huddersfield and obtained her PhD from the University of Bradford. Her research area includes Supply Chain Analytics, Artificial Intelligence and Sustainability. She has published in several leading peer-reviewed journals, including *Supply Chain Management: An International Journal.*

Samaila Ado Tenebe is a Lecturer at the National Open University of Nigeria (NOUN), specialising in Leadership and Management within the Agricultural and Hospitality sectors of Nigeria. Dr Samaila has three years of experience as a consultant with agricultural and hotel businesses and studies the value chain of agricultural products, with a specific focus on how leadership and technology can improve farm management practices, such as reducing pre- and post-harvest losses. Dr Samaila completed his PhD in 2019 from Queen Mary University of London (QMUL) in which he explored how farmers experience leadership within Nigeria's agricultural sector.

Nripendra P. Rana is a Professor in Marketing at the College of Business and Economics at Qatar University, Doha, Qatar. His current research interests focus primarily on consumer behaviour and decision-making, adoption of emerging ICTs and social media marketing. He has published more than 275 papers in a range of leading academic journals, conference proceedings, books, etc. He is a Chief Editor of *International Journal of Electronic Government Research* and an Associate Editor of *International Journal of Information Management*. He is also a Distinguished Visiting Professor at the University of Johannesburg, South Africa.

Uthayasankar Sivarajah is a Professor of Technology Management and Circular Economy at the University of Bradford. His passion for research and teaching is interdisciplinary in nature, focusing on the use of emerging digital technology for the betterment of society, be it in a business or government context. He has published over 50

Kamran Mahroof et al.

Supply Chain Management: An International Journal

Volume 29 · *Number* 3 · 2024 · 468–496

scientific articles in leading peer-reviewed journals and conferences. His research tackling societal challenges such as consumer behaviour and reduction of waste has featured in reputable media publications such as The World Economic Forum, BBC Yorkshire and The Conversation. He is a Fellow of the UK Higher Education Academy (FHEA) and a member of the British Academy of Management (BAM).

Vishanth Weerakkody is a Professor of Digital Governance at the School of Management in University of Bradford. His current research is truly multidisciplinary and centred around technology adoption and diffusion, social innovation, digital inclusion and public sector policy through disruptive technologies and digital government. He has secured multiple research grants in from the UK, European and International funding agencies and continues to work with industry and public sector to create practical-social impact through research. He has published in multiple high impact journals, including the *Journal of Information Technology, International Business Review, Information and Management, Production Planning and Control and Government Information Quarterly.*
